

Recursion

© A+ Computer Science - www.apluscompsci.com

Recursion

**Recursion occurs
when a method calls
itself.**

© A+ Computer Science - www.apluscompsci.com

If a method contains a call to itself, that method is recursive.
Recursion is a very useful programming tool if used properly.

```

public class RecursionOne
{
    public void run(int x)
    {
        out.println(x);
        run(x+1);
    }
    public static void main(String args[] )
    {
        RecursionOne test = new RecursionOne();
        test.run(1);
    }
}

```

Recursion

Will it stop?

OUTPUT

1
2
3
4
5

.....
stack overflow

© A+ Computer Science - www.apluscompsci.com

The recursive method `run()` will stop recurring when it runs out of memory. There is no code or case to make the recursion stop.

**open
recursionone.java**

© A+ Computer Science - www.apluscompsci.com

Base Case

A recursive method must have a stop condition/ base case.

Recursive calls will continue until the stop condition is met.

© A+ Computer Science - www.apluscompsci.com

Recursion 2

```
public class RecursionTwo
{
    public void run(int x )
    {
        out.println(x);
        if(x<5) ← base case
                run(x+1);
    }
    public static void main(String args[] )
    {
        RecursionTwo test = new RecursionTwo();
        test.run(1);
    }
}
```

OUTPUT

1
2
3
4
5

© A+ Computer Science - www.apluscompsci.com

Method `run()` has been improved as it now contains a case `(x<5)` that will prevent the recursion from going on to infinity.

The `println(x)` happens before the recursive call so the numbers appear in order.

Recursion 3

```
public class RecursionThree
{
    public void run(int x )
    {
        if(x<5) ← base case
            run(x+1);
        out.println(x);
    }
    public static void main(String args[] )
    {
        RecursionThree test = new RecursionThree ();
        test.run(1);
    }
}
```

OUTPUT

5
4
3
2
1

© A+ Computer Science - www.apluscompsci.com

Method `run()` has been improved as it now contains a case `(x<5)` that will prevent the recursion from going on to infinity.

The `println(x)` happens after the recursive call so the numbers appear in reverse order.

Recursion

**Recursion is basically
a loop that is created
using method calls.**

© A+ Computer Science - www.apluscompsci.com

```
class DoWhile
```

```
{
```

```
    public void run( )
```

```
    {
```

```
        int x=0;
```

```
        do{
```

```
            x++;
```

```
            out.println(x);
```

```
        }while(x<10);    //condition
```

```
    }
```

```
    public static void main(String args[] )
```

```
    {
```

```
        DoWhile test = new DoWhile();
```

```
        test.run( );
```

```
    }
```

```
}
```

do while

The Stack

When you call a method, an activation record for that method call is put on the stack with spots for all parameters/arguments being passed.

© A+ Computer Science - www.apluscompsci.com

The Stack

AR1- method() call

© A+ Computer Science - www.apluscompsci.com

Because AR1 is placed on the stack first, it will be the last AR removed from the stack.

The Stack

AR2- method() call

AR1- method() call

© A+ Computer Science - www.apluscompsci.com

Because AR2 is placed on the stack second, it will be the second to last AR removed from the stack.

The Stack

AR3- method() call

AR2- method() call

AR1- method() call

© A+ Computer Science - www.apluscompsci.com

The Stack

AR4- method() call

AR3- method() call

AR2- method() call

AR1- method() call

© A+ Computer Science - www.apluscompsci.com

AR4 is placed on the stack last and it is processed to completion first.

Once AR4 is finished, the execution sequence returns to AR3.

The Stack

AR3- method() call

AR2- method() call

AR1- method() call

© A+ Computer Science - www.apluscompsci.com

AR3 was placed on the stack 2nd to last and it is processed to completion after AR4 and before AR2.

Once AR3 is finished, the execution sequence returns to AR2.

The Stack

AR2- method() call

AR1- method() call

© A+ Computer Science - www.apluscompsci.com

AR2 was placed on the stack after AR1 and it is processed to completion after AR3 and before AR1.

The Stack

As each call to the method completes, the instance of that method is removed from the stack.

AR1- method() call

© A+ Computer Science - www.apluscompsci.com

Because AR1 was placed on the stack first, it is processed to completion last.

Recursion 2

```
public class RecursionTwo
{
    public void run(int x )
    {
        out.println(x);
        if(x<5) ← base case
                run(x+1);    It will stop!
    }
    public static void main(String args[] )
    {
        RecursionTwo test = new RecursionTwo();
        test.run(1);
    }
}
```

OUTPUT

1
2
3
4
5

© A+ Computer Science - www.apluscompsci.com

Because the `println(x)` is before the recursive call, x is printed before the next AR is created on the stack.

Recursion 3

```

public class RecursionThree
{
    public void run(int x )
    {
        if(x<5) ← base case
            run(x+1);
        out.println(x);
    }
    public static void main(String args[] )
    {
        RecursionThree test = new RecursionThree();
        test.run(1);
    }
}

```

OUTPUT

5
4
3
2
1

Why does this output differ from recur2?

© A+ Computer Science - www.apluscompsci.com

Because the `println(x)` is after the recursive call, the `println(x)` is delayed until the new AR is completed. The `println(x)` will happen when the AR above it has finished.

Tracing Recursive Code

```
int fun(int y)
{
    if(y<=1)
        return 1;
    else
        return fun(y-2) + y;
}
```

//test code in client class
out.println(test.fun(5));

AR3

y
1 return 1

AR2

y
3 return AR3 + 3 **4**

AR1

y
5 return AR2 + 5

9

As long as y is greater than 1, method fun() will continue to call itself creating recursion.

AR 1 - y = 5 return AR2 + 5

AR 2 - y = 3 return AR3 + 3

AR 3 - y = 1 return 1

Return 1 + 3 + 5

Tracing Recursive Code

```
int fun( int x, int y)
{
    if( y < 1)
        return x;
    else
        return fun( x, y - 2) + x;
}
```

//test code in client class
out.println(test.fun(4,3));

AR3		
x	y	
4	-1	return 4

AR2		
x	y	
4	1	return AR3 + 4

AR1		
x	y	
4	3	return AR2 + 4

12

Recursive Fun

```
int fun(int x, int y)
{
    if ( x == 0 )
        return x;
    else
        return x+fun(y-1,x);
}
```

OUTPUT

16

What would fun(4,4) return?

© A+ Computer Science - www.apluscompsci.com

**open
recursionsix.java**

© A+ Computer Science - www.apluscompsci.com

split recursion

tail recursion

```
public String recur(String s)
{
    int len = s.length();
    if(len>0)
        return recur(s.substring(0,len-1)) +
                s.charAt(len-1);
    return "";
}
```

© A+ Computer Science - www.apluscompsci.com

In the example above, the recursive call occurs before a letter is appended.

The example method above will return a new String containing the same letters as `s` in the exact same order as `s`.

AR1 - `s="bat" len=3 return AR2 + t`

AR2 - `s="ba" len=2 return AR3 + a`

AR3 - `s="b" len=1 return AR4 + b`

AR4 - `s="" len=0 return ""`

Final return `""+b+a+t`

split recursion

tail recursion

```
public String recur(String s)
{
    int len = s.length();
    if(len>0)
        return s.charAt(len-1) +
               recur(s.substring(0,len-1));
    return "";
}
```

© A+ Computer Science - www.apluscompsci.com

In the example above, the recursive call happens after a letter is appended.

The example method above will return a new String containing the same letters as `s` in the reverse order as `s`.

AR1 - `s="bat"` `len=3` `return t+AR2`

AR2 - `s="ba"` `len=2` `return a+AR3`

AR3 - `s="b"` `len=1` `return b+AR4`

AR4 - `s=""` `len=0` `return ""`

Final return `t+a+b+""`

The Stack

call out.println(recur("abc"))

OUTPUT

abc

AR1 – s="abc"
return abc

© A+ Computer Science - www.apluscompsci.com

What is the point?

If recursion is just a loop, why would you just not use a loop?

Recursion is a way to take a block of code and spawn copies of that block over and over again. This helps break a large problem down into smaller pieces.

© A+ Computer Science - www.apluscompsci.com

Using Recursion allows a section/block of code to be recreated while the program is running.

Each time the method is called, an instance of that method is created in memory. The size of the program can grow and shrink while the program is running.

A 10 line program might grow to a length of 1000 during run-time as recursive calls are made.

Counting Spots

If checking 0 0, you would
find 5 @s are connected.

@	-	@	-	-	@	-	@	@	@
@	@	@	-	@	@	-	@	-	@
-	-	-	-	-	-	-	@	@	@
-	@	@	@	@	@	-	@	-	@
-	@	-	@	-	@	-	@	-	@
@	@	@	@	@	@	-	@	@	@
-	@	-	@	-	@	-	-	-	@
-	@	@	@	-	@	-	-	-	-
-	@	-	@	-	@	-	@	@	@
-	@	@	@	@	@	-	@	@	@

@ at spot [0,0]
@ at spot [0,2]
@ at spot [1,0]
@ at spot [1,1]
@ at spot [1,2]

The exact same checks
are made at each spot.

Counting Spots

```

if ( r and c are in bounds and
    current spot is a @ )
    mark spot as visited
    bump up current count by one
    recur up
    recur down
    recur left
    recur right

```

This same block of code is recreated with each recursive call. The exact same code is used to check many different locations.

© A+ Computer Science - www.apluscompsci.com

Each time this section of code is called, it checks around it for matching cells.

If a matching cell is found, a recursive call is made on that cell to check for its neighbors. This process continues as long as matching cells are found.

The original method is very short, but the actual code being used can get quite long during run time as the code grows dynamically.

Counting Spots

if (r and c are in bounds and
current spot is a @)

mark spot as visited

bump up current count by one

recur up

recur down

recur left

recur right
